Solar ultraviolet and the occupational radiant exposure of  
Queensland school teachers: a comparative study between  
teaching classifications and behavior patterns

26 **Abstract**

27

28 Classroom teachers located in Queensland, Australia are exposed to high levels of  
29 ambient solar ultraviolet as part of the occupational requirement to provide  
30 supervision of children during lunch and break times. We investigated the relationship  
31 between periods of outdoor occupational radiant exposure and available ambient solar  
32 radiation across different teaching classifications and schools relative to the daily  
33 occupational solar ultraviolet radiation ( $H_{ICNIRP}$ ) protection standard of  $30 \text{ J/m}^2$ . Self-  
34 reported daily sun exposure habits ( $n=480$ ) and personal radiant exposures were  
35 monitored using calibrated polysulphone dosimeters ( $n=474$ ) in 57 teaching staff from  
36 6 different schools located in tropical north and southern Queensland. Daily radiant  
37 exposure patterns among teaching groups were compared to the ambient UV-Index.  
38 Personal sun exposures were stratified among teaching classifications, school  
39 location, school ownership (government vs non-government), and type (primary vs  
40 secondary). Median daily radiant exposures were  $15 \text{ J/m}^2$  and  $5 \text{ J/m}^2 H_{ICNIRP}$  for  
41 schools located in northern and southern Queensland respectively. Of the 474  
42 analyzed dosimeter-days, 23.0% were found to exceed the solar radiation protection  
43 standard, with the highest prevalence found among physical education teachers  
44 (57.4% dosimeter-days), followed by teacher aides (22.6 % dosimeter-days) and  
45 classroom teachers (18.1% dosimeter-days). In Queensland, peak outdoor exposure  
46 times of teaching staff correspond with periods of extreme UV-Index. The daily  
47 occupational  $H_{ICNIRP}$  radiant exposure standard was exceeded in all schools and in all  
48 teaching classifications.

49

50

51

52 **1. Introduction**

53

54 Limited data on solar ultraviolet radiation (UVR) radiant exposure in predominately  
55 indoor occupations highlights that skin cancer and eye disease are rarely considered  
56 diseases of occupation [1], yet skin cancer and chronic eye disease such as cataract,  
57 and pterygium are a probable consequence of lifetime exposure habits [2,3,4,5].  
58 Research measuring annual and/or lifetime UVR radiant exposure and evaluating the  
59 associated risks in workers with predominantly outdoor occupations are common.  
60 Such studies include: building and construction workers [6,7,8]; Lifeguards [9];  
61 Gardeners [10]; and Physical Education teachers [11,12]. Consequently, strong  
62 evidence is available correlating outdoor occupational radiant exposure with the  
63 incidence of non-melanocytic skin cancers. Much effort is required to reduce UVR  
64 radiant exposure in these occupations, particularly in tropical and sub-tropical regions  
65 which experience high levels of ambient solar radiation.

66

67 The intermittent sun exposure hypothesis, which places traditional indoor workers at  
68 higher risk, states that cumulative lifetime radiant exposure to solar-UVR, particularly  
69 episodes of sunburn, contribute to the risk of cutaneous melanoma in Caucasian  
70 populations [13,14,15]. Recent research by Kitchener [16] has shown there to be  
71 limited evidence of elevated risk of melanoma in Australian Navy personnel compared  
72 to the general population. The findings of this research, contribute toward a  
73 recognized complexity in associating occupational exposure, whether acute, chronic  
74 or intermittent with increased melanoma skin cancer risk [17,18,19]. The Kitchener  
75 [16] study did however associate a higher risk of melanoma for Naval personnel who

76 spent most of their working life out of direct sunlight. That intermittent exposures  
77 among workers who spend most of their time indoors cannot be excluded as a risk  
78 factor for the development of melanoma, particularly in populations exposed to high  
79 ambient levels of UVR [20,21,22] makes Classroom teachers an interesting case for  
80 studying occupational radiant exposure. The traditional role of a classroom teacher  
81 encompasses supervising children in the playground during meal breaks that generally  
82 coincide with peak ambient solar-UVR intensity. In Queensland, Australia melanoma  
83 rates are among the highest in the world [23,24,25]. Personal radiant exposures  
84 received as a consequence of the occupational requirement to be outdoors during  
85 periods of peak ambient UVR intensity highlight the potential value of collecting  
86 baseline information that may be used to advocate behavioral changes aimed at  
87 reducing melanoma risk [26,27], and reduced risk of keratinocyte cancers [28, 29].

88

89 Queensland employers are legally obliged to provide a working environment that  
90 prevents the injury or illness of workers according to the Work Health and Safety Act  
91 [30]. Solar-UVR radiant exposure, received as a consequence of the occupational  
92 requirement to provide a duty of care to Queensland school children carries the  
93 potential to cause harm to teachers due the high levels of ambient solar radiation in  
94 school playgrounds [31,32,33]. The responsibility of employers to provide a safe  
95 working environment highlighted in recent research shows that an increasing number  
96 of successful worker's compensation claims in Australia have been reported for skin  
97 damage resulting from radiant exposure to UVR in the workplace [34]. A position  
98 statement by the Cancer Council Australia [35], recommends that workplaces have a  
99 comprehensive sun protection program incorporating: assessment of UVR exposure  
100 risks, implementation of protective control measures, education and training for

101 employees and the development of written policy. Teachers and teacher aides, as  
102 employees are bound by the policies of their designated workplaces and are therefore  
103 a population group that have the potential to adopt and follow measures aimed at  
104 reducing personal solar-UVR radiant exposure. The role teaching staff play in  
105 demonstrating sun safe behavior to school children is also recognized as one of  
106 several relevant intervention strategies actively encouraged and supported by the  
107 National ‘SunSmart Schools’ program which has been credited with reducing skin  
108 cancer incidence in Australia since its inception in 1988 [36,37].

109

110 We report objective measurements of the Spring-time occupational radiant exposure  
111 of primary school teachers, teacher aides, and secondary school teachers from sites in  
112 tropical (Townsville) and sub-tropical (Toowoomba) Queensland separated by 8.2  
113 degrees of latitude. Radiant exposures are referenced relative to the Australian  
114 Radiation Protection Standard (ARPS) [38] and the erythemal action spectrum [39].  
115 For studies in which the personal risk of erythema is of concern, the erythemally  
116 effective [39] radiant exposure is often cited rather than ARPS, although the later is  
117 more relevant in occupational radiant exposure studies. The ARPS specifically  
118 weights solar UV radiant exposure to the hazard sensitivity spectrum of the  
119 International Commission on Non-Ionizing Radiation Protection [40] for the skin and  
120 eye. According to the standard, exposure of the skin to solar radiation must not  
121 exceed a weighted daily UV radiant exposure of  $30 \text{ J/m}^2$ . Below this limit, the risk of  
122 detectable acute or delayed effects are considered extremely small [41].

123

124

125

126 **2. Materials and Methods**

127

128 *2.1 Study Location*

129 The northern Australian state of Queensland, located between the latitude of 10°S and  
130 28°S experiences a warm tropical to sub-tropical climate, a high number of sunshine  
131 days and extreme solar UV-levels annually from September through to April in the  
132 austral spring, summer and autumn seasons. In this research solar UV radiant  
133 exposures were monitored at two sites over a wide latitudinal range in 57 workers  
134 employed in teaching roles in November toward the end of the 2014 school semester  
135 from schools located in Townsville (19.3°S 146.8°E) and Toowoomba (27.5°S,  
136 151.9°E).

137

138 Townsville, a major regional city of 170 000 residents is located in the dry tropics  
139 along the north Queensland coast. The monthly average UV-Index range over the year  
140 in Townsville ranges from 6-13, whilst the daily maximum UV-Index is typically  
141 between 10 and 13 during November when this study was conducted [42].

142

143 Toowoomba has a similarly large regional population of 110 000 residents and is  
144 located approximately 120 km inland of the capital city of Brisbane in the south-east  
145 of the state. Elevated to an altitude of 690 m, Toowoomba experiences a temperate  
146 seasonal climate with cooler winters and a larger annual variability in the UV-Index.  
147 The monthly average peak UV-Index across the year ranges from 6-11, whilst  
148 Toowoomba's typical maximum November UV-Index ranges between 10 and 11  
149 [43].

150

151 *2.2 Monitoring Ambient solar-UVR*

152 The University of Southern Queensland (USQ) and James Cook University (JCU)  
153 campuses, located in Townsville and Toowoomba have access to ambient erythemally  
154 weighted solar UV data monitored continuously and averaged every 10 minutes by  
155 model 501 Solar light Co (Philadelphia, PA) broadband radiometers. Instruments at  
156 both campuses are located on university building rooftop environments with  
157 unobstructed sky views. Access to the JCU radiometer was made through the  
158 Australian Radiation Protection and Nuclear Safety Authority public website [42].  
159 The Toowoomba radiometer is maintained by the USQ solar radiation research group.  
160 Personal radiant exposure measurements expressed relative to the available ambient  
161 UVR were determined by comparison to UV-Index measurements recorded by these  
162 instruments for the period 7:00 am to 5:00 pm.

163

164

165 *2.3 Participants*

166 Human ethics research approvals were obtained from the University of Southern  
167 Queensland (USQ) H14REA089; The Queensland Department of Education, Training  
168 and Employment ref11/54273 and 550/27/1497; and the Catholic Education Office  
169 (Townsville Diocese) 2007-15, to approach schools and recruit volunteer study  
170 participants. Primary (prep – grade 7 in 2014; students generally 5-12 years-old) and  
171 secondary school teachers (grades 8-12 in 2014) and primary teacher aides working  
172 full-time or part-time (at least 3 days per week) were selected to participate over a  
173 period of two weeks (10 working days). Eligible participants working in teaching  
174 roles were recruited from a convenience sample of 6 government and non-government

175 schools located within 15 km of ambient solar UV monitoring equipment located at  
 176 either JCU's, Townsville campus or the USQ's, Toowoomba campus.

177

178 Each school was visited by a member of the research team and meetings were  
 179 conducted with all available teaching staff to recruit volunteers. A total of 57 eligible  
 180 staff provided written informed consent to participate and were issued with study  
 181 information packs including a 10-day sun diary and 10 personal dosimeter badges.  
 182 Participants from Townsville and Toowoomba were instructed to wear a new  
 183 dosimeter daily for ten working days from 10 to 21 November, 2014. Study  
 184 participants were classified as classroom teachers, outdoor Physical  
 185 Education/Agriculture (PE / Ag) specialist teachers or teacher aides. The occupational  
 186 radiant exposure of one school principal was also measured (Table 1).

187

188

189 Table 1: Characteristics of participating schools and teaching/support staff in Townsville and  
 190 Toowoomba, Queensland, Australia, stratified by region.

191

	Total N (%)	Townsville (19.3°S) N (%)	Toowoomba (27.5°S) N (%)
<b>School Characteristics (n=6)</b>			
Government	5 (83.3)	2 (66.7)	3 (100%)
Non-Government	1 (16.7)	1 (33.3)	0
Primary	4 (66.7)	2 (66.7)	1 (33.3)

197

#### 198 *2.4 Sun Diaries and UV Dosimeters*

199 The pattern of sun exposure of each of the 57 participants was monitored through the  
200 use of personal UV dosimeters and the completion of daily sun exposure diaries on  
201 scheduled workdays. Sun exposure diaries were divided into 15 minute intervals from  
202 7:00 am to 5:00 pm. Participants were instructed to indicate periods of time outdoors  
203 of at least 5 minutes duration by proportional shading of 15 minute time intervals  
204 indicated on the sun exposure diary. Thus, '0 minutes' could be recorded as a possible  
205 daily exposure time, but brief intermittent periods of exposure of less than 5 minutes  
206 duration were not expected to be noted by the study participants. Outdoor periods  
207 were defined for the purposes of this study as those areas not inside a building and  
208 may have included open playground areas, as well as shaded and semi-shaded  
209 undercover areas including walkways and areas protected by shade sails.

210

211 Personal solar UV radiant exposures were monitored using polysulphone film (PS)  
212 dosimeters with daily radiant exposure results being expressed in dosimeter-days. The  
213 dosimeters are manufactured at the USQ Solar Radiation Research Laboratory from  
214 PS film cast to a thickness of 40 µm and adhered to flexible frames measuring 15 by  
215 10 mm. The lightweight frames have a clear aperture of 6 mm and have been used  
216 successfully for personal radiant exposure measurements in similar studies [33,44,45].

217

218 Participants were instructed on completing daily sun diaries and the use of the  
219 dosimeters, including correct handling and storage, at the beginning of the study.  
220 Participants retained sun exposure diaries and dosimeter packs at school, attaching  
221 new dosimeters to the upper shoulder (in a horizontal plane using a safety pin) at the  
222 commencement of each working day. Dosimeters were stored by participants in  
223 supplied envelopes out of direct sunlight before leaving school. Dosimeters and  
224 diaries were collected from participants at the end of the study period. All post  
225 exposure measurements of dosimeters were conducted at the same time, two weeks  
226 after the study period to ensure consistency in the time between the end of the radiant  
227 exposure period and the absorbance measurements.

228

229

### 230 *2.5 Measurement of erythemal and ICNIRP UV radiant exposure*

231 PS film was selected for use as a dosimeter in the current study due to the physical  
232 dynamic range and suitability of PS for short term daily radiant exposure monitoring  
233 [46]. PS film experiences a measurable change in absorbency ( $\Delta A$ ) at 330 nm that  
234 was calibrated to the spectrally weighted UV radiant exposure. The ultraviolet radiant  
235 exposure in  $J/m^2$  was determined by integration of the weighted irradiance with  
236 respect to time,  $t$ . Here,  $H_{CIE}$  is the erythemally effective radiant exposure according  
237 to the International Commission on Illumination [39] and  $H_{ICNIRP}$  is actinic effective  
238 radiant exposure according to the ICNIRP [40], reiterated by Directive 2006/25/EC  
239 [47] and specifically referenced by the ARPS, where

240

$$H_{CIE/ICNIRP} = \int_{t_1}^{t_2} E_{CIE/ICNIRP}(t) dt. \quad (1)$$

241

242  $E_{CIE}(t)$  or  $E_{ICNIRP}(t)$  is the weighted UV irradiance at any given time in the integral,  
243 calculated by summation in the UV waveband of the spectral UV irradiance,  $E(\lambda)$   
244 after weighting to the relevant action spectrum,  $S_{CIE}(\lambda)$  [39] or  $S_{ICNIRP}(\lambda)$  [40].

245

$$E_{CIE/ICNIRP} = \sum_{\lambda=280}^{400} S_{CIE/ICNIRP}(\lambda)E(\lambda)\Delta\lambda \quad (2)$$

246

247 The  $H_{CIE}$  and  $H_{ICNIRP}$  radiant exposures were included in this research to allow direct  
248 comparison of personal radiant exposures to the erythemally effective ambient UV,  
249 and the ARPS occupational radiant exposure limit [38]. Because the change in film  
250 absorbency is dependent on the spectral characteristics of the UV source [48],  
251 separate calibrations were made for both Toowoomba and Townsville. The  
252 spectroradiometer and calibration process for film dosimeters have previously been  
253 described in detail [33,49]. Calibration characteristics for personal dosimeters  
254 traceable to the University of Southern Queensland's scanning spectroradiometer  
255 (model DTM300, Bentham Instruments, Reading UK) are included in supplementary  
256 material.

257

258

### 259 **3. Results**

260

#### 261 *3.1 Response*

262 A total of 474 dosimeters were returned from the 570 dosimeters distributed to  
263 participants (83.2% response rate). Non-return of dosimeters was primarily due to the

264 inclusion of 12 part-time staff (worked <10 days per fortnight; Table 1), in addition to  
265 unscheduled staff absences due to sickness etc, and damage/loss of a small proportion  
266 of badges (5 dosimeters).

267

### 268 3.2 Distribution of personal UV radiant exposures and time spent outdoors

269 The median  $H_{ICNIRP}$  received by all teachers across both locations was  $11 \text{ J/m}^2$ , (IQR:  
270  $2\text{-}28 \text{ J/m}^2$ ) per day. The measured personal radiant exposures were shown to  
271 approximate a log-normal distribution with the peak of the distribution coinciding  
272 with the median (Figure 1). The median self-reported exposure time determined from  
273 480 returned sun exposure diaries was 30 minutes (IQR: 0 to 60 minutes) (Figure 2).  
274 The study medians equate to an approximate  $H_{ICNIRP}$  radiant exposure rate of  $4 \text{ J/m}^2$   
275 per 10 minutes, roughly the equivalent of  $14 \text{ J/m}^2 H_{CIE}$  per 10 minutes.

276

277

278 Figure 1: Distribution of ICNIRP Spring dosimeter-day radiant exposures,  $H_{ICNIRP}$  ( $n = 474$ ) for all  
279 participants in Townsville and Toowoomba, Queensland, Australia.

280

281

282 Figure 2: Distribution of self-reported daily outdoor exposure times for all participants in Townsville  
 283 and Toowoomba (Queensland, Australia) over the 2-week period in late Spring (10-21 November)  
 284 2014.

285

286 A total of 49 (10.3%)  $H_{ICNIRP}$  radiant exposures fell between the range of 0 and 0.1  
 287  $J/m^2$ . These results are representative of teaching staff that did not spend any  
 288 significant periods of time outdoors during the working day. In total, 122 (25.4%)  
 289 zero minute daily exposure time records were self-reported from the 480 returned sun  
 290 diaries. Failure to report intermittent outdoor sun exposure times during the working  
 291 day, or the contribution of stray radiant exposures received while attaching or  
 292 removing dosimeters may have contributed to higher radiant exposures being  
 293 recorded on self reported nil exposure time days.

294

295

### 296 3.3 Differences in UV radiant exposure by teaching role

297 Participant radiant exposure results, expressed as the number of dosimeter-days are  
 298 summarized in Table 2. The table includes the ICNIRP and CIE calibrated personal  
 299 radiant exposure. It also includes the percentage erythemal ambient radiant exposure  
 300 fraction calculated with respect to the daily erythemal radiant exposure measured on a

301 horizontal plane by the ARPANSA JCU and USQ broadband radiometers from 7:00  
 302 am to 6:00 pm.

303

304

305 Table 2: Distribution of the ICNIRP and erythemally effective ultraviolet radiant exposures per  
 306 dosimeter-day in late Spring in Townsville and Toowoomba, Queensland, Australia, shown by study-  
 307 site and teaching staff classification.

308

Participants	dosimeter- days N (%)	ICNIRP <sup>a</sup> radiant exposure (J/m <sup>2</sup> )		Erythema radiant exposure (J/m <sup>2</sup> )		Percentage ambient <sup>b</sup>	
		median	IQR	median	IQR	Median	IQR
<b>Townsville (19.3°S)</b>							
Classroom Teacher	185 (39.0)	11.7	4.0-26.8	40.2	11.8-95.8	0.8	0.2-1.7
PE Teacher	14 (3.0)	53.4	37.8-63.2	192.5	136.4-227.8	3.4	2.4-4.2
Teacher Aide	62 (13.1)	19.9	10.7-28.9	71.7	38.7-104.0	1.3	0.7-1.8

PE / Ag Teacher	40 (8.4)	25.7	4.7-75.4	90.4	16.7-265.5	1.7	0.3-5.2

309

310 Footnotes:

311 <sup>a</sup> ICNIRP International Commission on Non-Ionizing Radiation Protection spectral weighting function.

312 <sup>b</sup> The percentage of the radiant exposure of the dosimeters relative to the ambient is for the erythemally  
 313 effective radiant exposures.

314

315

316 Classroom teachers recorded lower personal Spring-time UV radiant exposures than  
 317 other teaching classifications. The median UV radiant exposures of classroom  
 318 teachers in both Townsville and Toowoomba were less than the daily ARPS limit of  
 319 30 J/m<sup>2</sup> (Table 2). Comparison of these data by region revealed that the median  
 320 personal  $H_{ICNIRP}$  of Toowoomba classroom teachers in late Spring was approximately

321 three times lower than the radiant exposure received by Townsville classroom  
322 teachers. The difference in measured radiant exposures between the classroom teacher  
323 groups was statistically significant ( $p < 0.0003$ ) for both the erythemally effective and  
324 ICNIRP radiant exposure, where comparative significance was determined in this  
325 study according to the Mann-Whitney U test.

326

327 Physical Education (PE) / Agriculture (Ag) specialist teachers in Toowoomba  
328 received approximately half the  $H_{ICNIRP}$  of the PE teachers located in Townsville ( $p <$   
329  $0.0709$ ) with a corresponding reduction in the median erythemal ambient radiant  
330 exposure fraction, decreasing from 3.4% in Townsville to 1.7% in Toowoomba. PE /  
331 Ag teacher specialists received the highest radiant exposures of all staff groups with  
332 median radiant exposures in Townsville exceeding the occupational radiant exposure  
333 limit ( $53.4 \text{ J/m}^2$ , IQR:  $37.8\text{-}63.2 \text{ J/m}^2$ ) and reaching  $25.7 \text{ J/m}^2$  (IQR:  $4.7\text{-}75.4 \text{ J/m}^2$ ) in  
334 Toowoomba. Comparison of median  $H_{ICNIRP}$  and  $H_{CIE}$  radiant exposures show that PE  
335 teachers received personal radiant exposures that were approximately five times  
336 higher than those recorded for classroom teachers (Table 2). Classroom teachers were  
337 the dominate study group, comprising 42 volunteer participants compared with PE /  
338 Ag specialists and Teacher Aides, making up a total of 14 participants (Table 1).  
339 Despite their small number, the 116 returned dosimeters of PE / Ag teachers and  
340 Teacher aides recorded the highest radiant exposures of all study sub groups.

341

342 Teacher aides were found to have the second highest personal radiant exposures after  
343 the PE / Ag teachers. Their median fractional ambient radiant exposure was found to  
344 be between the classroom and PE/ Ag teacher groups at 1.3% (IQR: 0.7-1.8%). The  
345 median  $H_{ICNIRP}$  radiant exposure for the teacher aides was under the ARPS at 19.9

346 J/m<sup>2</sup> (IQR: 10.7 to 28.9 J/m<sup>2</sup>). Compared with the teacher aides, the median personal  
347  $H_{ICNIRP}$  radiant exposure of the school principal monitored for the ten days of the  
348 November study period was well under the radiant exposure standard at 4.0 J/m<sup>2</sup>  
349 (IQR: 0.2-9.3 J/m<sup>2</sup>).

350

351

### 352 *3.4 Differences in radiant exposure limits by location and school characteristics*

353 Differences in measured personal radiant exposure and self-reported outdoor exposure  
354 time varied by location (Table 3). Median  $H_{ICNIRP}$  radiant exposures for all staff  
355 groups were 15 J/m<sup>2</sup> (IQR: 5-29 J/m<sup>2</sup>) and 5 J/m<sup>2</sup> (IQR:1-23 J/m<sup>2</sup>) for Townsville and  
356 Toowoomba, respectively. These radiant exposures were achieved during a median  
357 self-reported total daily outdoor exposure time of 30 minutes (IQR: 0-60 minutes) for  
358 Townsville participants and 23 minutes (IQR: 0-55 minutes) for Toowoomba  
359 participants, indicating the reduction in personal  $H_{ICNIRP}$  radiant exposure between  
360 locations may be largely due to differences in exposure pattern.

361

362 The proportion of teachers exceeding the daily ARPS was consistently higher in  
363 Townsville than in Toowoomba (Table 3). A total of 24% of the participant radiant  
364 exposures in Townsville exceeded the standard compared with 21.2% of radiant  
365 exposures in the Toowoomba cohort. These proportions varied depending on teaching  
366 staff classification. Dosimeters returned from classroom teachers showed a clear  
367 trend, with 20.5% of personal radiant exposures in Townsville exceeding the limit  
368 compared with 15.3% of dosimeters returned by classroom teachers from  
369 Toowoomba. More than twice as many of the dosimeters returned by PE teachers in

370 Townsville (92.9%) exceeded the limit compared with those from PE / Ag teachers in  
 371 Toowoomba (45%).

372

373

374 Table 3: Summary of dosimeter radiant exposures exceeding the ICNIRP daily radiant exposure limit  
 375 N, stratified by location and school characteristics for Classroom and Physical Education (PE) /  
 376 Agriculture (Ag) teacher classifications. Percentages expressed relative to *n*, the total number of radiant  
 377 exposure records for each category.

378

Participants	Location		P value <sup>a</sup>	School type		P value <sup>a</sup>	School ownership		P value <sup>a</sup>
	Townsville (19.3°S) N/n (%)	Toowoomba (27.5°S) N/n (%)		Primary N/n (%)	Secondary N/n (%)		Government N/n (%)	Non- government N/n (%)	
All participants	66/271 (24.4)	43/203 (21.2)	0.0003	67 /300 (22.3)	42/174 (24.1)	0.6412	101/421 (24.0)	8/53 (15.1)	0.8140
Classroom Teacher	38/185 (20.5)	25/163 (15.3)	0.0003	39/214 (18.2)	24/134 (17.9)	0.3969	55/295 (18.6)	8/53 (15.1)	0.2117
PE/ Ag Teacher	13/14 (92.9)	18/40 <sup>b</sup> (45)	0.0709	13/14 (92.9)	18/40 (45)	0.0709	31/54 (57.4)	-	-

379

380 Footnotes:

381 <sup>a</sup> P values are Mann-Whitney U test comparisons of ICNIRP radiant exposures for all dosimeter records  
 382 (n) in each category.

383 <sup>b</sup> Toowoomba sample includes 1 Agriculture teacher

384

385

386 The proportion of dosimeter-days exceeding the daily ARPS occupational radiant  
 387 exposure limit was similar for primary and secondary schools, with 22.3% of the  
 388 dosimeters returned by primary school staff and 24.1% of the dosimeters returned by  
 389 secondary school staff exceeding 30 J/m<sup>2</sup> *H*<sub>ICNIRP</sub> (Table 3). The proportion of  
 390 dosimeters exceeding the limit was approximately 18% for both primary and  
 391 secondary classroom teachers (Table 3). The radiant exposure limit comparison

392 between primary and secondary school PE / Ag teachers mirrored the differences by  
393 study-site, as all primary PE teachers included in the study were based in Townsville  
394 and all of the secondary PE / Ag teachers were located in Toowoomba. Comparison  
395 of personal radiant exposure with school ownership also did not reveal any significant  
396 differences although fewer non-government employees than government employees  
397 exceeded the daily occupational ARPS radiant exposure limit (Table 3). Of the 53  
398 returned dosimeters from non-government classroom teachers, 15.1% were found to  
399 exceed the radiant exposure standard compared with 18.6% of the 295 returned  
400 dosimeters from classroom teachers employed in government schools ( $p < 0.2117$ ).

401

402

### 403 *3.5 The Radiation Protection Standard and outdoor exposure time*

404 Collectively, 109 (23%) dosimeter records were found to exceed the ARPS radiant  
405 exposure limit of  $30 \text{ J/m}^2$ . Self-reported exposure times for staff exceeding the limit  
406 ranged from 0 to 270 minutes with a corresponding median exposure time of 60  
407 minutes (IQR: 30-90 minutes). Teaching staff found to have personal  $H_{ICNRP}$  radiant  
408 exposures under the daily ARPS radiant exposure limit spent between 0 and 125  
409 minutes outdoors, with a median exposure time of 15 minutes (IQR: 0-39 minutes).  
410 Participants were not required to report exposure times less than 5 minutes, raising the  
411 possibility that actual exposure times may be slightly greater than reported here.  
412 There was however a clear statistical significance in the self-reported exposure times  
413 between the dosimeter-days exceeding the standard compared to those not exceeding  
414 the standard ( $p < 0.0001$ ) with little observed overlap of the IQR. These results are  
415 indicative of the influence of total daily exposure time, with participants exposing

416 themselves for longer periods being more likely to exceed the daily ARPS radiant  
417 exposure limit.

418

419 The proportion of dosimeter-days exceeding the ARPS daily radiant exposure limit  
420 was also shown to be dependent on teaching staff classification with 54.7% of  
421 dosimeter-days for PE / Ag teachers exceeding the limit compared with only 22.6% of  
422 dosimeter-days for teacher aides, 18.1% of dosimeter days for classroom teachers and  
423 10% of dosimeter days for the school principal.

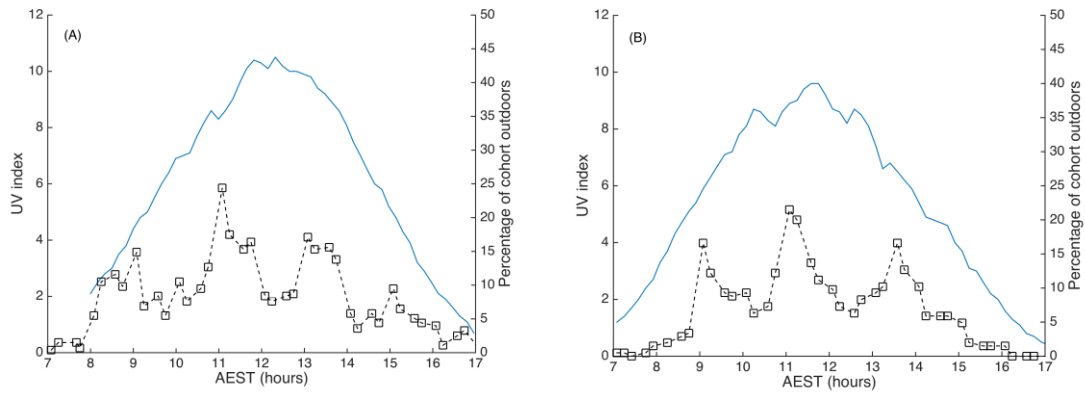

424

425

### 426 *3.6 General patterns in UV radiant exposure versus exposure time*

427 Figure 3 shows the number of self-reported teacher daily exposure times, expressed as  
428 a percentage of the number of returned sun exposure diaries against the time of day  
429 (Australian Eastern Standard Time). Importantly, the highest number of daily sun  
430 exposure records were found to occur between 11:00 am and 11:15 am, corresponding  
431 with peak ambient radiant exposure time as shown by the mean UV-Index calculated  
432 over the study period and plotted in the figure for Townsville and Toowoomba.  
433 Outdoor activity peaks were also found to occur near 1:30 pm in both locations. The  
434 timing of exposure for all participants corresponds roughly with school meal break  
435 times.

436

437 Figure 3: Average UV index and percentage of cohort outdoors expressed relative to daily Australian  
 438 Eastern Standard Time (AEST) during the November study period in (A) Townsville and (B)  
 439 Toowoomba, Queensland, Australia.

440

441

### 442 3.7 The influence of exposure timing

443 The total number of self-reported outdoor exposure times, stratified by exposure  
 444 duration is provided in Table 4. Overall, 31.9% of all sun diaries reported that  
 445 participants spent between 5 and 30 minutes outdoors per day. This finding was  
 446 reflected by teaching classification, for classroom teachers (34.8%), and teacher aides  
 447 (33.9%), with both groups spending between 5 and 30 minutes outdoors daily.

448

449

450

451

452

453

454

455

456

457 Table 4: Summary of self-reported daily outdoor exposure time records for all study participants in  
 458 Townsville and Toowoomba, Queensland, Australia, stratified by teaching staff classifications.

459

Participants	N (%)	Daily exposure categories			
		(≤ 5 min) N (%)	(> 5 and ≤ 30 min) N (%)	(> 30 and ≤ 60 min) N (%)	(> 1 hour) N (%)
All participants	480 (100)	130 (27.1)	153 (31.9)	93 (19.4)	104 (21.7)
Classroom Teacher	353 (73.5)	96 (27.2)	123 (34.8)	68 (19.3)	66 (18.7)
PE / Ag Teacher	55 (11.5)	12 (21.8)	7 (12.7)	6 (10.9)	30 (54.5)
Teacher Aide	62 (12.9)	15 (24.2)	21 (33.9)	18 (29.0)	8 (12.9)
Principal	10 (2.1)	7 (70)	2 (20)	1 (10)	0 (0)

460

461

462 PE / Ag teachers were at the highest risk of exceeding the ARPS with 54.5% of this  
 463 group spending more than 1 hour per day outdoors. Teacher aides were at moderate  
 464 risk of exceeding the daily occupational radiant exposure limit, with 29.0% of sun  
 465 diaries reporting outdoor exposure durations of between 30 to 60 minutes and 12.9%  
 466 reporting outdoor exposure periods of more than 1 hour. This result is similar to that  
 467 of the classroom teachers, although a slightly higher combined percentage of teacher  
 468 aides were found to self-report outdoor exposure times above 30 and 60 minutes. The  
 469 school principal spent the least time outdoors, with most reported outdoor exposures  
 470 being less than 5 minutes per day (70% of self-reported exposure records).

471

472 The influence of daily exposure timing was considered for all participants with self-  
 473 reported outdoor exposure times of up to the study median of 30 minutes. Given  
 474 school hours in Queensland occur within peak UV exposure periods (between 9:00  
 475 am and 3:00 pm) and often occur when the UV-Index is 3 or greater (i.e. sun-  
 476 protection required),  $H_{ICNIRP}$  radiant exposures of less than 30 minutes duration were

477 examined between 11:00 am and 2:00 pm (highest likely  $H_{ICNIRP}$  radiant exposure  
 478 risk) and for self-reported exposures up to 30 minutes received outside this time  
 479 (lower  $H_{ICNIRP}$  risk) (Table 5). The likelihood of dosimeter-days exceeding the  
 480 occupational radiant exposure limit was found to depend on time of day. Of all of the  
 481 study participants receiving up to 30 minutes daily exposure, 18.7% exceeded the  
 482 ARPS if their radiant exposure occurred exclusively between 11:00 am and 2:00 pm  
 483 compared with 8.3% of study participants who received up to 30 minutes daily  
 484 exposure outside of these times ( $p < 0.0175$ ). This finding indicates that outdoor  
 485 exposures up to 30 minutes duration are more likely to exceed the daily occupational  
 486 radiant exposure limit of  $30 \text{ J/m}^2$  if teachers are exposed between 11:00 am and 2:00  
 487 pm. These times correspond with meal and lunch break periods.

488

489

490 Table 5: Summary of  $H_{ICNIRP}$  actinic radiant exposures above or below the Australian Radiation  
 491 Protection Standard of  $30 \text{ J/m}^2$  for participants outdoors for up to 30 minutes. Data is stratified by  
 492 timing of outdoor exposure.

493

Participants	High Risk (outdoors between 11:00 am to 2:00 pm)			Low Risk (not outdoors between 11:00 am to 2:00 pm)			P value <sup>a</sup>
	N (%)	Above EL	Below EL	N (%)	Above EL	Below EL	
All participants	91 (100)	17 (18.7)	74 (81.3)	36 (100)	3 (8.3)	33 (91.7)	0.0175
Classroom Teacher	77 (84.6)	15 (19.5)	62 (80.5)	30 (83.3)	3 (11.1)	27 (88.9)	0.0057
PE / Ag Teacher	4 (4.4)	1 (25)	3 (75)	2 (5.6)	0 (0)	2 (100)	0.5333
Teacher Aide	10 (11.0)	1 (10)	9 (90)	4 (11.1)	0 (0)	4 (100)	0.1419

494

495 Footnotes:

496 <sup>a</sup> P values are Mann-Whitney U test comparisons of all (N) high risk to low risk ICNIRP radiant  
497 exposures.

498 <sup>b</sup> Principal did not spend up to 30 minutes outdoors for either risk condition.

499

500

501

#### 502 **4. Discussion**

503

504 Classroom teachers, as a group have not been studied extensively with reference to  
505 ICNIRP radiant exposure limits. Several studies have concluded that radiant  
506 exposures received by indoor workers receive between 0 and 4% of the available  
507 ambient UVR [50,51], however these studies do not weight measured radiant  
508 exposures specifically to the ICNIRP [40] action spectrum. To ascertain UVR radiant  
509 exposure risk in the workplace, internationally recognized radiant exposure safety  
510 standards should be applied. The ICNIRP standard applied here and reiterated in the  
511 ARPS [38] has determined specifically the number of employees exceeding  
512 recommended radiant exposure limits. Of the 23.0% of teaching staff found to receive  
513 radiant exposures over the limit, most were PE / Ag specialist teachers. This did not  
514 however exclude classroom teachers or teacher aides from exceeding occupational  
515 standards.

516

517 Collectively, study participants were found to receive approximately 4 J/m<sup>2</sup> per 10  
518 minutes of outdoor radiant exposure. Based on this exposure rate, the teachers in this  
519 study would be expected to exceed the ARPS of 30 J/m<sup>2</sup> in 70 to 80 minutes outdoor  
520 exposure time. Given the  $H_{ICNIRP}$  to  $H_{CIE}$  varies by a factor of 3 to 4 for most periods  
521 of the day outside twilight hours and low solar elevations [7] and given a likely

522 November daily peak UV-Index of 10 ( $0.25 \text{ W/m}^2 H_{CIE}$ ), the expected ambient  
523  $H_{ICNIRP}$  under these conditions would roughly correspond to  $0.07 \text{ W/m}^2$ . Under these  
524 conditions the ARPS, weighted with respect to the  $H_{ICNIRP}$  would be exceeded in a  
525 little over 7 minutes (429 seconds). The study median outdoor exposure times for  
526 those participants found to exceed the ARPS was 60 minutes. These results reflect the  
527 protective (indoor or shade seeking) exposure habits of the group as a whole. This  
528 group consisted mainly of classroom teachers (73.7%).

529

530 All teachers that spent more than 2 hours outside daily exceeded the occupational  
531 radiant exposure standard. The study median radiant exposure time of participants  
532 over the ARPS was 60 minutes. A statistically significant number of daily exposure  
533 records were found to exceed the ARPS limit in less than 30 minutes for those  
534 teachers who self-reported outdoor radiant exposure times exclusively between 11:00  
535 am and 2:00 pm. A significant point of difference in the current study to other  
536 occupational groups is that whereas meal times represent times of reduced UV radiant  
537 exposure in other outdoor occupations [8], they represent periods of increased radiant  
538 exposure for school teaching staff. Teachers employed in Queensland are entitled to  
539 30 minutes daily for meal breaks between 11:30 am and 2:00 pm although no limit is  
540 given to the number of outdoor playground duties a teacher may be required to  
541 supervise [52,53]. The requirement of meal breaks to be taken between 11:30 am and  
542 2:00 pm is likely to be a contributing factor to the high number of playground  
543 supervisions (and therefore outdoor exposures) observed between 11:00 am and 1:30  
544 pm. Using our study sample as a guide, teachers performing a single, hourly yard duty  
545 on any one day of the week would be at significant risk of exceeding the daily  
546 occupational radiant exposure limit.

547

548 Some differences in the number of participants exceeding the ARPS were found  
549 between different participant classifications. PE / Ag teachers were at particular risk,  
550 spending for the most part, more than 30 minutes daily outdoors. This result is a likely  
551 consequence of playground supervision requirements for PE / Ag teachers coupled  
552 with the necessity to spend a greater proportion of the day outdoors supervising sport  
553 or agriculture lessons. Removal of the requirement of PE / Ag teachers to conduct  
554 playground duty during the working week would clearly contribute to a reduction in  
555 occupational radiant exposure risk for this group and would make an important  
556 contribution to school workplace health and safety policies.

557

558 A new study group, not previously investigated in UV exposure research were the  
559 teacher aides. This participant group recorded the second highest  $H_{ICNIRP}$  radiant  
560 exposure after the PE / Ag specialist teachers. In Queensland, it is currently a  
561 requirement of teacher aides to supervise children during breaks [54]. This does not  
562 preclude supervision during meal breaks. Given that most of the teacher aides in our  
563 study were found to be outside for greater than 30 minutes indicates that the children  
564 they supervise on a day-to-day basis are also likely to be spending this amount of time  
565 outdoors. This makes this particular group an interesting cohort to follow in future  
566 studies.

567

568 Difference in geographical latitude between Townsville and Toowoomba could not be  
569 isolated as an exclusive factor associated with the likelihood of exceeding the  
570 occupational radiant exposure standard. That personal radiant exposures in tropical  
571 north Queensland were higher than those measured in southern Queensland for all

572 teaching classifications is likely to be attributed to behavior differences and total daily  
573 radiant exposure time variation between groups. The relative ambient radiant  
574 exposure fractions of classroom teachers (Table 1) support the notion that participants  
575 in the Toowoomba group were more likely to stay indoors under comparatively  
576 similar ambient conditions, with the UV-Index reaching a maximum daily average of  
577 10.5 in Townsville and 9.6 in Toowoomba during the study period. Although low  
578 ambient exposure fractions are consistent with the findings of research reported by  
579 other authors, the findings of our study highlight that occupational radiant exposures  
580 received by teaching staff occur in or near lunch break periods. This places staff  
581 required to supervise children at these times at greater risk of exceeding occupational  
582 radiant exposure standards.

583

584

## 585 **5. Conclusions**

586

587 The findings of the current study provide baseline information on occupational radiant  
588 exposures and behavior patterns of teachers from schools located in a warm, and high  
589 ambient UV climate. This information is relevant to teaching staff working in tropical  
590 and subtropical locations and may be indicative of radiant exposure patterns likely to  
591 be observed by staff working in an increasingly warmer and variable global climate.

592

593 A clear strategy that would have a measureable impact on reducing the number of  
594 staff exceeding the ARPS would involve reducing the total amount of time spent  
595 outdoors. This strategy, along with sun exposure minimization, improved  
596 identification and sun exposure awareness training for workers, and the mandatory

597 use of personal protective equipment will assist in guiding the development of more  
598 comprehensive school policies that aim to reduce the potential of staff to exceed  
599 recommended radiant exposure limits [55]. Given that most teachers were found to be  
600 entering outdoor environments during peak UV-Index periods, strategies which aim to  
601 minimize radiant exposure during school break times are the most likely to have a  
602 positive impact on improving the occupational health outcomes of Queensland  
603 teachers.

604

605

## 606 **6. Acknowledgments**

607 The authors acknowledge the support of participant school principals and school staff  
608 for their valuable contribution to this work. We also thank JCU research assistant,  
609 Hilla Cohen for her contribution and data analysis assistance. Travel costs and  
610 collaboration between JCU and USQ research staff was supported by a Research  
611 Infrastructure Block Grant from JCU, and a Research Incentive Activation Scheme  
612 and Research Giants Travel Award from USQ. The authors declare they have no  
613 actual or potential competing financial interests.
